<b>(54) Title:</b> EXTERIOR AUTOMOTIVE LAMINATE WITH PRESSURE-SENSITIVE ADHESIVE  <div style="text-align: center;"> </div>		
<b>(57) Abstract</b>  <p>A flexible decorative sheet for use in surfacing an automobile body panel includes a first polyester carrier sheet (10) having a high gloss surface, a clear coat (12) of a weatherable optically-clear polymer containing fluorocarbon resin and an acrylic resin coated on the surface of the first carrier sheet, a tie coat (14) on the clear coat, and a color coat (16) containing a chlorinated polymer with dispersed pigments cast on the tie coat and dried. A pressure-sensitive adhesive layer (18) is formed on a second polyester carrier sheet (20) and then laminated to the exposed face of the color coat to form a pressure-sensitive, adhesive-backed composite paint coat between the outer carrier sheets which form protective removable backing sheets for the resulting laminate. The decorative sheet is applied to a substrate panel by pressure-sensitive adhesive bonding techniques, with the clear coat serving as a glossy, weatherable protective outer layer for the underlying color coat. The PVC-containing color coat enhances room temperature elongation of the finished film to enable application of the laminate to three-dimensionally contoured surfaces. The resulting paintfinish has a defect-free, weatherable and durable outer surface with high gloss and high distinctness of image, meeting requirements for exterior automotive use.</p>

**EXTERIOR AUTOMOTIVE LAMINATE WITH  
PRESSURE-SENSITIVE ADHESIVE****FIELD OF THE INVENTION**

This invention relates generally to dry paint transfer techniques, and more particularly, to the use of these techniques to decorate exterior car body members or panels with a paint coat applied in a separate production operation. The invention can eliminate or reduce the painting steps carried out in the manufacturing operations of a conventional automobile production plant.

**BACKGROUND OF THE INVENTION**

Automotive design and manufacture present a unique set of problems in the selection of materials and processes used in the manufacture of automobile bodies. As a form of transportation, automobiles are unique because most buyers want a vehicle to have a certain individual styling. A recent trend in the automobile industry is toward production of distinctive vehicles styled to attract specific groups of consumers. This change has required the car builder to shift production from a few models manufactured in large volumes to a larger number of more distinctive body styles. These developments have demanded from the manufacturer both styling flexibility and reasonable tooling costs for each body style.

For many years, the primary method of applying a paint coat to an automobile was through a spray painting process. However, several recent developments make the spray painting process more difficult. First, many states have enacted environmental protection laws restricting the amount of volatile organic content (VOC) a paint may contain. Second, spray painting is more suited to larger production runs where unique body styling is not needed. Third, higher energy costs have driven up costs for production paint lines where high temperature ovens must be used to cure the paint coat. These factors are especially pronounced in two tone painting applications, where the automobile must pass through the paint line twice.

-2-

1 Development of a production process to replace the spray painting line requires  
addressing a number of technical problems. A potential replacement process must provide  
both environmental and cost advantages to the automaker before the process can receive  
consideration. It must also meet all of the quality standards for exterior automotive coatings.  
5 For example, a coating must have the appearance and durability characteristics comparable  
to a spray painted coating. It must also possess a number of important physical properties  
such as: high gloss, hardness, distinctness-of-image (DOI), abrasion resistance, weatherability  
(such as UV resistance), impact strength, thermal stability, gasoline and acid resistance,  
cleanability, adhesion to the substrate, resistance to water and humidity exposure, and hiding  
10 ability or opacity of the coating.

In the past, a conventional production process for applying an exterior paint coat to car  
bodies made of sheet metal has involved transporting the preformed auto bodies to application  
lines in the plant where the car bodies are dipped in paint, followed by transporting them to  
a separate location for baking the paint coat and waiting until the hardened paint coat dries  
15 thoroughly. Most paint systems today are acrylic enamels which are cross-linked into a hard,  
glossy, durable paint coat during baking. Following painting, the car bodies are transported  
back to the production plant for further assembly operations. Conventional painting of sheet  
metal car bodies is expensive and is a significant factory problem with respect to  
environmental protection, worker safety, corrosion treatment, and waste disposal. It has been  
20 estimated that about one-third of the total capital investment in an automobile production  
facility today is involved in painting car body members and panels.

If a coating process can be developed as an alternative to conventional auto painting,  
then automobile assembly plants can be more compact, and environmental and safety  
problems associated with conventional car painting at the factory site may be avoided.

25 Many corporate product development efforts have sought alternatives to conventional  
painting of exterior car body panels and parts. A number of problems must be overcome to  
develop an economical production-type paint system and process that can eliminate  
conventional spray painting operations. One approach, which is the subject of this invention,  
involves developing a paint-coated film which can be used to replace a conventional painted  
30 finish on the exterior of an automobile body. The film is made from a paint coat applied to  
a casting sheet. The paint coat is dried and then transferred from the casting sheet to the  
exterior car body panel. The coating operation permits use of high temperature-resistant paint  
systems capable of producing a tough, glossy finish. The film is coated with a pressure  
sensitive adhesive which allows the film to be transferred from the casting sheet and bonded  
35 to the exterior car body panel. One use of such a paint-coated film is to replace the separate  
painting step of a conventional two-tone paint coat process.

1 A number of technical problems must be overcome in order to use such a film for  
exterior automotive applications. For instance, the film must be defect-free before being  
applied. The film also must initially be repositionable. Therefore, the adhesive should have  
5 a relatively low initial tack value which increases over time and therefore becomes  
increasingly more difficult to remove. The film must avoid long-term delamination at the  
adhesive interface between the film and the car body panel; and inter-layer delamination  
between the various coatings in the finished composite film also must be avoided.

Durability properties are also critical in producing a paint coat capable of exterior  
automotive use. The paint coat must avoid exhibiting defects when exposed to mechanical  
10 impact and avoid deterioration of the surface from exposure to chemicals and to the weather.  
Among other properties, the film requires good cleanability, UV and heat resistance.

A paint system that produces the toughness or hardness necessary for exterior  
automotive use also must have the elongation properties necessary for applying the film  
around complex three-dimensional shapes without cracking, or producing stress lines or other  
15 surface non-uniformities. Certain paint films having good elongation at elevated temperatures  
are not necessarily applicable to the present invention which requires good elongation at room  
temperatures.

Thus, the desired paint system should have a critical combination of many physical  
properties in order to produce a surface capable of exterior automotive use, while retaining  
20 the desired surface characteristics after the application process. However, some physical  
properties tend to be mutually incompatible in such a process. For instance, a paint system  
may have good durability properties such as hardness, toughness, weatherability and the like;  
but the same paint system may not have sufficient room temperature elongation to be applied  
smoothly over a complex shape by a pressure-sensitive adhesive. Some paint systems have  
25 sufficient elongation to permit application over a complex shape, but they are too soft and  
therefore lacking in the necessary hardness and/or durability properties.

In summary, there is a need for an economical production process for decorating  
contoured exterior car body members or panels with a paint coat having both the durability  
and appearance properties necessary for exterior automotive use. Techniques for applying  
30 a paint coat to such a part can provide a valuable alternative to conventional spray painting  
of exterior car body members. Capital costs also can be reduced and environmental problems  
can be alleviated. Applying such a paint film requires, however, a paint system and  
processing techniques capable of producing a finished film having a combination of good  
durability, elongation, opacity, gloss and DOI levels, and a defect-free surface. The present  
35 invention solves these problems.

## SUMMARY OF THE INVENTION

Briefly, one embodiment of this invention provides a process for manufacturing a flexible film having a finished paint coat with exterior automotive quality durability, gloss, distinctness-of-image (DOI) and other appearance characteristics in the finished paint coat. In this process, the paint coat is applied to an exterior automotive panel by applying pressure to the film, which is bonded to the substrate by a pressure sensitive adhesive. The invention is described herein in the context of a paint coat applied to the surface of car body member or panel, but the invention is also applicable to other articles of manufacture having a paint coat with properties similar to those required for exterior automotive use.

Considering the application of the invention to a process for applying the film to an exterior car body panel, a paint coat comprising a synthetic resinous material is coated in thin-film form onto a flexible, heat-resistant temporary casting sheet. The paint coat is dried on the casting sheet sufficiently to transfer a predetermined exterior surface smoothness from the casting sheet to the paint coat. The paint coat may comprise a clear coat and a separate pigmented color coat, as well as a thin film-form intervening tie coat to bond the clear coat and the color coat. The color coat, in combination with the clear coat, provides a composite paint coat having the durability, gloss, DOI and other appearance properties necessary for exterior automotive use. The tie coat inhibits interlayer delamination between the clear coat and the color coat. A pressure sensitive adhesive is formed on a casting sheet in a separate coating and drying operation. The adhesive layer is then transfer-laminated to the color coat side of the composite paint coat. During the laminating process, the composite paint coat retains the durability, gloss, DOI and other appearance properties necessary for exterior automotive applications. The finished composite adhesive-backed paint film is capable of elongating sufficiently to conform to three-dimensionally contoured substrate panels without significant loss of exterior automotive appearance and durability properties, including weatherability.

In one embodiment, the clear coat portion of the paint coat comprises a blended fluorinated polymer and acrylic resin-containing paint system with thermoplastic properties. The relative amounts of the fluorinated polymer and acrylic resin components in the paint coat formulation provide a sufficient level of elongation for the film to be applied to complex three-dimensional shapes, in combination with a properly selected color coat, while providing sufficient durability and appearance properties for the finished film to be useful on an exterior car body panel.

In one form of the invention, the fluorinated polymer component comprises polyvinylidene fluoride (PVDF), and the acrylic resin component can be a polymethyl methacrylate resin, a polyethyl methacrylate resin, or mixtures thereof, including copolymers thereof. One finished product having a surface capable of exterior automotive use is made

1 from a paint system comprising from about 50% to about 75% PVDF and from about 25%  
to about 50% acrylic resin, by weight of the total PVDF and acrylic solids.

5 Certain PVDF-acrylic clear coat formulations have good exterior appearance and  
durability properties, but room temperature elongation may not be at levels sufficient for the  
end-use of adhering smoothly to contoured surfaces. In one embodiment, it has been  
discovered that certain color coat formulations (in which the underlying color coat is bonded  
to the outer clear coat as described above) can enhance elongation of the overall composite  
10 paint film, including enhancing elongation of the PVDF-acrylic outer clear coat. One such  
color coat includes a chlorinated polymer-containing resin, such as polyvinyl chloride (PVC),  
which enhances elongation of the finished composite laminate without significant degradation  
of exterior automotive durability and appearance properties. In other cases the elongation-  
enhancing color coat can comprise a thermoplastic fluorinated polymer and acrylic resin-  
containing paint system, or an acrylic-based ink, or a paint coat containing polyurethane.  
15 Pigmented dispersions contained in the color coat also in some instances inhibit plasticizer  
migration which prevents intercoat adhesion failure. Use of certain plasticizers also inhibits  
plasticizer migration during use, which can inhibit volatile haze problems as well as  
preventing interlayer adhesion failure.

20 In a further embodiment, a first color coat comprising a fluorinated polymer and an  
acrylic resin can be bonded to the outer clear coat, while the tie coat bonds a second color  
coat comprising the chlorinated polymer to the first color coat. The elongation-enhancing  
second color coat provides enhanced elongation properties to the clear coat and the first color  
coat, and therefore, improves elongation of the finished laminate. The pigments contained  
in the first color coat can provide UV protection for the second color coat containing the  
chlorinated polymer. UV absorbers can be used in the second color coat. Interlayer  
25 delamination is prevented by such UV protection.

30 Thus, the present invention provides a process and articles of manufacture in which a  
paint coat ultimately forms an exterior finish on a contoured surface of an exterior car body  
panel, although the paint coat also is applicable to flat surfaces. During application to a  
contoured surface, the paint coat has sufficient elongation to retain the durability and  
appearance properties to be useful as a finished exterior paint coat for a car body panel.

These and other aspects of the invention will be more fully understood by referring to  
the following detailed description and the accompanying drawings.

#### **BRIEF DESCRIPTION OF THE DRAWINGS**

35 FIG. 1 is a schematic cross-sectional view illustrating one embodiment of a paint-coated  
composite laminate according to principles of this invention. Film thicknesses are  
exaggerated in size and not to scale, for simplicity.

1           FIGS. 2-5 are further schematic cross-sectional views illustrating various embodiments of the paint-coated laminate.

          FIG. 6 is a schematic cross-sectional view illustrating a paint-coating step in the process of forming the paint-coated laminates of this invention.

5           FIG. 7 is a schematic elevational view illustrating a laminating step in the process of this invention.

#### **DETAILED DESCRIPTION**

10           A paint coat with a surface capable of exterior automotive use is applied to a molded plastic substrate panel by the processing steps described below. FIGS. 1 through 5 illustrate various embodiments of a dry paint transfer laminate used in the process of applying a finished exterior automotive paint coat to the substrate panel. FIG. 1 illustrates one embodiment of the invention which includes, in combination, a flexible, foldable, heat-resistant, self-supporting first carrier sheet 10, also referred to in the art as a casting sheet, and a transferable, adherent, flexible composite paint coat coated onto one surface of 15 the first carrier sheet. The paint coat is a self-supporting, flexible synthetic resinous dry film-form coating. The paint coat can be formed in many embodiments described in FIGS. 1 through 5; but referring initially to the embodiment of FIG. 1, the composite paint coat includes a clear coat 12 coated on the carrier sheet 10 and dried; a tie coat 14 coated on the dried clear coat; and a color coat 16 coated on the dried tie coat, in which the intervening tie coat provides a means of bonding the color coat and the clear coat. A layer of pressure-sensitive adhesive 18 is adhered to the side of the color coat opposite from the clear coat; and a second flexible, foldable, heat-resistant, self-supporting carrier sheet 20 supports the adhesive layer 18. In one embodiment, the adhesive layer 18 is separately coated on the 20 second carrier sheet 20 and dried, followed by laminating the adhesive 18 to the color coat 16. The outer carrier sheets 10 and 20 provide exterior protection for the composite paint coat and its adhesive layer in a manner similar to a removable backing sheet. The second carrier sheet 20 is silicone coated to provide release properties for the adhesive layer 18.

25           The carrier sheet 10 comprises a polyester casting film having a high gloss surface. The carrier can be a polyester film such as Mylar (a trademark of Du Pont), American Hoechst 3000 grade polyester film, more preferably Hoechst 3900 grade polyester film, or the like. The preferred film thickness of the carrier sheet is about 2-3 mils. Polyester films are preferred because the high gloss surface is capable of transferring a high gloss level to a surface of the clear coat 12 in contact with the carrier, where the transferred smoothness is sufficient for exterior automotive use. The polyester carrier film has a sufficiently high 30 heat resistance to resist axial elongation under temperatures applied during subsequent paint coat drying steps. The clear coat may be applied to the polyester carrier film without a

1 release coat on the high gloss surface of the carrier. The formulation of the clear coat is such  
that the clear coat can be easily transferred from the carrier sheet and can replicate the highly  
smooth surface of the carrier after the clear coat dries and after subsequent dry paint transfer  
steps in which the paint coat is released from the carrier, as described below. The carrier  
5 sheet 20 also comprises a polyester film similar to the polyester carrier sheet 10 except for  
the silicone coated release surface for the adhesive layer. The polyester carrier sheets 10 and  
20 serve as removable protective outer backing sheets in the combination shown in FIG. 1.  
The polyester carrier sheets are critical for high distinctness-of-image (DOI) applications  
because they impart high DOI to the finished composite sheet. The clear coat cast on the  
10 carrier sheet 10 has a smooth surface from replicating the surface of the carrier. The  
adhesive coat also has a smooth surface when cast on a polyester carrier. These factors  
enhance DOI. Conventional backing sheets such as those made of paper stock can transfer  
surface non-uniformities to the paint coat and the adhesive and thereby reduce DOI.

15 As an optional step, a thin film of wax (not shown) can be coated on the first carrier  
sheet 10 and dried, followed by coating the clear coat over the thin film of wax. The wax  
is coated in a film thickness (less than 0.01 mil and preferably 0.001 mil) that avoids any  
adverse effect on the clear coat replicating the surface gloss of the carrier.

#### Clear Coat

20 The clear coat is a transparent or substantially transparent thermoplastic synthetic  
resinous coating composition coated in thin film form onto the surface of the carrier sheet in  
a liquid state. Heat is later applied to the clear coat to dry it, without cross-linking the resin,  
while the clear coat is on the carrier. The preferred dry film thickness of the clear coat is  
about 0.8 mil. to 1.4 mils. Preferably, the clear coat is coated onto the first carrier sheet 10  
25 by a reverse roll coating process illustrated in FIG. 6, although the clear coat can be applied  
by other methods, rather than conventional coating or casting techniques. Referring to the  
reverse roll coating process of FIG. 6, the clear coat lacquer is contained in a coating pan 22  
having a lacquer inlet 24 in the main portion of the pan, and a lacquer drain 26 on an  
opposite side of a weir 28. An applicator roll 30 rotates to pick up the lacquer from the pan  
30 and coat it onto a previously uncoated polyester film 10 which passes over a guide roll 32 and  
then passes between the applicator roll and a rubber back-up roll 34. A metering roll 36  
adjacent the applicator roll 30 rotates in the same direction as the applicator roll. A doctor  
blade 38 wipes the surface of the metering roll to properly control the thickness of the coating  
on the applicator roll. The adjustable gap between the metering roll and the applicator roll  
35 controls the thickness of the coating on the surface of the applicator roll. The coating picked  
up by the applicator roll is then coated onto the polyester film 10 as the film passes into

1 contact with the reverse-rotating applicator roll. The applied coating on the film is shown at  
40. The coated film then passes to a drying oven.

5 The clear coat is dried at oven temperatures in the range from about 250°F to about  
400°F. Preferably, the clear coat is dried in multiple zones spaced apart along the long axis  
of the paint-coated carrier in line with the reverse roll coater. A preferred drying technique  
involves use of three heating zones with a progressively higher temperature applied in each  
successive zone. The solvent contained in the clear coat is essentially all driven off in the  
multistage drying process. The same multistage drying process is used for drying the tie coat  
14, the color coat 16 and other coatings used in the various embodiments described below.  
10 The polyester carrier is resistant to heat at temperatures up to about 400°F so that the carrier  
does not deform dimensionally during the drying step. The polyester carrier film thickness  
of about 2-3 mils assists the film in resisting elongation during drying. This ensures a high  
gloss level being replicated by the surface of the dried clear coat from the high gloss surface  
of the carrier. This also makes it possible to use high temperature resistant, high gloss paint  
15 systems which cannot be applied to and dried on plastic substrates directly because of  
temperature limitations of the plastic substrate materials.

The clear coat formulation produces a dry film-form exterior film which, in  
combination with the underlying color coat, produces a composite paint coat having properties  
useful as an exterior automotive paint coat. The properties of such an exterior automotive  
20 paint coat are described in PCT Publication WO 88/07416 generally from pages 20 through  
23 of that publication. The disclosure of the entire PCT publication, Application  
PCT/US88/00991, dated 25 March 1988, is incorporated herein by this reference.

In one embodiment, the clear coat 12 comprises a blend of a thermoplastic fluorinated  
polymer and an acrylic resin. The clear coat preferably contains the fluorinated polymer and  
25 acrylic resin as its principal components. The fluorinated polymer component is preferably  
a thermoplastic fluorocarbon such as polyvinylidene fluoride (PVDF). The fluorinated  
polymer also can include copolymers and terpolymers of vinylidene fluoride. The  
thermoplastic fluorocarbon useful in the clear coat is the polyvinylidene fluoride known as  
Kynar, a trademark of Pennwalt Corp. This polymer is a high molecular weight (400,000)  
30 polymer which provides a useful blend of durability and chemical resistance properties.  
Generally, a high molecular weight PVDF resin, with a weight average molecular weight of  
about 200,000 to about 600,000 is used.

The acrylic resin component of the clear coat can be a polymethyl methacrylate, or  
a polyethyl methacrylate resin, or mixtures thereof, including methacrylate copolymer resins,  
35 acrylate resins, and minor amounts of other comonomers. The clear coat also can include  
minor amounts of block copolymers and/or compatibilizers to stabilize the blended PVDF and  
acrylic resin system and provide compatibility between films.

1           In one embodiment, a principal component of the acrylic resin contained in the clear  
coat is a medium molecular weight polymethyl methacrylate resin such as Elvacite 2010, a  
trademark of Du Pont. (In all further references to Elvacite resins herein, it should be noted  
that Elvacite is a trademark of Du Pont for a group of its acrylic resins.) In another  
5           embodiment, a principal component of the acrylic resin for the clear coat can be a high  
molecular weight polyethyl methacrylate resin such as Elvacite 2042. The acrylic component  
of the clear coat also can comprise a mixture of Elvacite 2010 and a medium-to-high  
molecular weight polymethyl methacrylate resin such as Elvacite 2021. In a further  
embodiment, the acrylic resin component can comprise Elvacite 2042 and a low molecular  
10          weight polyethyl methacrylate resin such as Elvacite 2043. Other similar combinations of  
acrylic resins, their homopolymers and copolymers, may be used as a component of the clear  
coat. Generally, the acrylic resin component has a relatively high weight average molecular  
weight of about 50,000 to about 400,000.

15          The PVDF and acrylic-based clear coat formulation can be prepared as a solution of  
PVDF and acrylic resin in solvent. Experimental tests of finished car body panels, in which  
the paint coat has been prepared from a solution of PVDF in acrylic resin, have demonstrated  
high levels of gloss and DOI.

20          The PVDF and acrylic-based clear coat formulation also can be prepared as a  
dispersion of the PVDF in a solution of the acrylic resin. In one embodiment, the clear coat  
formulation can be prepared by mixing the acrylic resin with a suitable organic solvent and  
applying heat to dissolve the resin. The mixture is then allowed to cool sufficiently before  
adding the PVDF component so that the PVDF will not dissolve, but will be maintained as  
a dispersion in the acrylic-solvent based mixture. By maintaining the PVDF component as  
a dispersion in the clear coat, solvent evaporation during drying of the clear coat can be  
25          improved.

30          A preferred composition of the dried clear coat comprises from about 50% to about  
75% PVDF, and from about 25% to about 50% acrylic resin, by weight. In some instances,  
the maximum content of the PVDF component is about 72%, with the balance essentially  
comprising the acrylic resin. These solids ranges are based on the relative proportions of the  
PVDF and acrylic components only in the clear coat formulation. Other minor amounts of  
solids, such as UV stabilizers, block copolymers and compatibilizers also may be contained  
in the clear coat formulation.

35          In one embodiment, a successful experimental car body panel having exterior  
automotive surface properties was coated with a paint system in which the dried clear coat  
consisted essentially of about 65% PVDF and about 35% polyethyl methacrylate resin, by  
weight. This clear coat provided high gloss and good exterior automotive properties of  
appearance and durability. In another successful experimental car body panel having good

1 exterior automotive appearance and durability properties, including gloss, the dried clear coat consisted essentially of about 72% PVDF and about 28% polyethyl methacrylate resin, by weight.

5 The acrylic resin component of the clear coat is desirable because of its compatibility with the PVDF in dry film form. The acrylic resin is also added in an amount that yields a transparent clear coat in dry film form. Generally speaking, transparency and DOI of the composite paint coat increase in proportion to the amount of acrylic resin added to the PVDF-acrylic system. It has been determined that a pure PVDF clear coat has reasonably good properties of durability and elongation, but such a 100% PVDF coating is not normally transparent. When sufficient acrylic resin is added to the PVDF component, the resulting clear coat becomes reasonably transparent. Increased transparency of the clear coat improves the gloss level of the finished clear coat. The acrylic resin is also combined with the PVDF in an amount that maintains sufficient elongation to allow the clear coat (and the color coat to which it is bonded) to be applied (as part of the construction described below) to complex three-dimensional shapes, while retaining the exterior automotive durability properties and appearance properties, including gloss and DOI, of the finished paint coat. It has been determined that a dry film-form PVDF-acrylic-based clear coat containing about 28-35% acrylic resin and about 65% to 72% PVDF, by weight of the total PVDF and acrylic solids, will yield sufficient elongation.

20 The PVDF component of the clear coat is desirable because of the exterior automotive durability properties it provides in the resulting clear coat, particularly in combination with the acrylic resin component. Elongation at room temperatures is within desired levels, when the PVDF-acrylic clear coat is combined with a color coat having elongation-enhancing properties as described below. The PVDF component also provides good weatherability properties in the finished paint coat. It has been determined that a pure thermoplastic acrylic resin clear coat can provide good hardness or toughness characteristics, but it lacks weatherability. A cross-linked thermoset acrylic resin commonly used as an exterior auto paint is not useful in the process of this invention. When elongated, it shatters or cracks. A dry film-form PVDF and acrylic resin-containing clear coat having from about 25% to about 50% acrylic resin (by weight of the total PVDF-acrylic-based solids) has sufficient elongation to allow proper application, while maintaining the exterior automotive durability, gloss and DOI, and other appearance properties of the finished composite paint coat.

30 It is possible to produce low DOI products both with and without the PVDF-acrylic outer clear coat. For instance, a pigmented PVDF-acrylic outer color coat can be used in the finished product, but it will have a lower gloss and DOI and generally a dull appearance. The PVDF-acrylic outer clear coat is necessary where exterior automotive quality high gloss and DOI and good appearance are necessary.

### Tie Coat

An acrylic-based tie coat 14 bonds the color coat 16 to the clear coat 12. The tie coat is applied by coating it directly to the clear coat by a reverse roll coat or gravure printing process. The preferred film thickness of the tie coat is about 0.1 to 0.4 mil. The tie coat is essentially transparent so that the color coat 16 is visible through the clear coat 12 and the underlying tie coat 14. The tie coat provides a critical function of enhancing interlayer bonding between the clear coat 12 and the color coat 16, where the clear coat and color coat are comprised of different polymers. The tie coat also is used for interlayer bonding of two color coats comprised of different polymers, as with a further embodiment described below. The tie coat formulation also is described in the examples to follow.

### Color Coat

The color coat 16 is preferably applied by reverse roller coating techniques similar to those illustrated in FIG. 6. A preferred dry film thickness of the color coat 16 is in the range of about 1.5 to about 2.5 mils. The color coat comprises a flexible synthetic resinous coating composition containing a sufficient amount of uniformly dispersed pigment to provide the appearance necessary for exterior automotive use. More specifically, the color coat contains an amount of dispersed pigment such that the composite paint coat maintains opacity and high DOI throughout the application step so as to ultimately provide a finished paint coat with exterior automotive properties. The resinous material contained in the color coat functions in combination with the clear coat to produce the required exterior automotive surface for the finished paint coat. That is, although the clear coat provides the exterior surface portion of the finished paint coat, the exterior automotive properties of the finished paint coat are not controlled solely by the clear coat formulation. The underlying color coat can affect DOI and durability properties of the finished paint coat, for example. Abrasion resistance is an example of a mechanical property enhanced by a tougher color coat in combination with the exterior clear coat. Weatherability of the finished paint coat also is influenced by the color coat formulation as well as the clear coat. The color coat also comprises a thermoplastic resinous material which is capable of elongation at application temperatures (typically room temperatures) while not significantly disrupting the exterior automotive properties of the finished paint coat. The color coat can enhance elongation of the clear coat and therefore improve overall elongation of the finished paint-coated composite laminate, as described below.

The color coat is preferably dried by passing it through the same multiple heating zones used in drying the clear coat. Drying temperatures in each of the zones are progressively increased and are at slightly higher temperatures than those used for drying the clear coat. The color coat is preferably cast directly on the tie coat, as opposed to forming

1 the color coat as a separate film and then laminating it to the tie coat. This has been found  
to enhance interlayer bonding and thereby inhibit delamination during use. The color coat  
composition is preferably a synthetic resinous coating composition having thermoplastic  
properties similar to the clear coat. Although the color coat alone does not necessarily  
5 require all of the exterior automotive properties of durability and appearance, in order to  
produce a useful composite paint coat, a color coat composition (exclusive of the pigment  
contained in the coating) having most of the desirable exterior automotive durability  
properties is preferred.

10 In the embodiment illustrated in FIG. 1, the color coat 16 provides the function of  
enhancing elongation of the finished laminate. To achieve this function, the color coat  
contains a thermoplastic chlorinated polymer, preferably polyvinyl chloride (PVC). Such a  
PVC-containing color coat has been found useful as a means of improving room temperature  
elongation of the finished paint-coated composite laminate. In particular, it enhances  
elongation when used in combination with the PVDF-acrylic outer clear coat, or when used  
15 in combination with an overlying PVDF-acrylic color coat. On the other hand, use of a  
PVC-containing polymer for an exterior automotive composite paint coat can have UV and  
heat resistance problems. To avoid these problems, the PVC-containing color coat is not used  
as an exterior coat, but rather an underlying film bonded to the overlying PVDF-acrylic coat  
or coats. The flexibility-enhancing formulation of the color coat 16 can be prepared by  
20 mixing the chlorinated component, along with various additives, such as plasticizers and heat  
and light stabilizers, in suitable organic solvents. The preferred chlorinated polymer  
component for the color coat is a polyvinyl chloride homopolymer resin such as Geon 199,  
a trademark of B. F. Goodrich Chemical Co. The resin component can include a minor  
percentage of an acrylic component. Suitable organic solvents include a non-polar solvent  
25 comprising an aromatic petroleum distillate such as Hi-Sol 10, a trademark of Ashland  
Chemical Co.

The plasticizers contained in the thermoplastic chlorinated polymer formulation enhance  
elongation and flexibility properties of the color coat. The particular plasticizers used in the  
formulation are those that avoid significant migration during use. Such plasticizer migration  
30 can cause interlayer delamination and volatile haze problems in the finished product. Use of  
certain high molecular weight plasticizers have been found to inhibit plasticizer migration.  
Plasticizers with a molecular weight greater than about 7,000 can produce good plasticizer  
permanence. In one embodiment, a plasticizer comprising polyester azelates (propylene  
glycol azelaic acids) having a molecular weight of 7,080 produced good migration resistance  
35 and good resistance to volatile haze and interlayer delamination problems, as demonstrated  
in the examples to follow.

1           The color coat may contain a substantial pigment level in order to provide sufficient  
opacity to maintain desirable coloration in the finished article. In a highly contoured three  
dimensionally shaped article, a large amount of pigment may be necessary for hiding,  
5           following subsequent application steps. For most colors, a pigment level from about 2% to  
about 30%, by weight of the solids contained in the coating produces the desired opacity in  
the finished paint coat. The amount of pigment used varies depending upon the color. For  
a white color coat used over an experimental car body panel, for example, a pigment level  
of about 30%, by weight of the total solids, was used. For a black color coat using carbon  
black pigment applied over an experimental car body panel, about 2% pigment was used.

10           The pigment contained in the color coat can affect exterior automotive properties. For  
instance, different pigments, even of the same color, can vary widely with respect to their  
resistance to weathering, particularly UV weatherability. The pigments dispersed in the color  
coat may retain the plasticizer and, thereby, may prevent plasticizer migration which can  
cause intercoat adhesion and volatile haze problems. The PVC-containing color coat has  
15           produced good results in terms of heat and light resistance and weatherability of the finished  
paint coat.

          The high pigment level in the color coat also can affect mechanical properties of the  
coating, such as durability and elongation. Elongation properties also should not be adversely  
affected by added pigments or stabilizers.

20           Thus, the desired color coat formulation provides the appearance and durability  
properties which, in combination with the clear coat, produce a composite paint coat having  
the properties suitable for exterior automotive use. These include high gloss, DOI and  
weatherability. The color coat enhances elongation of the combined clear coat and color coat  
while durability and appearance properties, including gloss and DOI, of the finished paint coat  
25           are not degraded. During use, the paint coat can be subjected to elongation in order to  
conform to three-dimensionally contoured surfaces. Such elongation of the finished laminate  
can be achieved without disruption of the necessary exterior automotive properties even under  
extremes of heat, cold and humidity. For instance, tests have shown that the finished product  
comprising the laminate shown in FIG. 1 can undergo elongation in a range of about 50%  
30           to about 150% greater than its original dimension with no noticeable color change (for certain  
pigment dispersions) and suitable retention of most appearance properties such as color, gloss  
and DOI. In one embodiment, a construction was made from a color coat having PVC in the  
range of about 35% to about 50% of the total solids contained in the color coat formulation  
(including the pigment). This construction produced a finished paint coat having durability  
35           and appearance properties, including high gloss and DOI, sufficient for exterior automotive  
use following application as a pressure-sensitive adhesive-backed decorative sheet to a  
contoured surface.

1 As an alternative to the PVC component, the color coat also can contain other resin  
formulations. A flexible acrylic or urethane resin with good room temperature elongation  
properties also may be useful as a color coat formulation. In addition, the PVC-containing  
color coat may be used in combination with one or more overlying pigmented paint coat  
5 layers of different resin formulations. As one example, the pigmented chlorinated polymer  
color coat can be one of several color coats in a finished laminate. It can be used with one  
or more overlying color coats containing a blended fluorinated polymer and acrylic resin.  
In this instance, the tie coat bonds the pigmented chlorinated polymer color coat to the  
adjacent color coat of a different polymer. The combined color coats work in combination  
10 to enhance coloration and opacity of the finished product. The chlorinated polymer color coat  
enhances flexibility of the finished paint coat laminate.

Although the paint coat has thus far been described in relation to a clear coat and a  
separate color coat, the composite paint coat of this invention also may be produced with the  
color coat being replaced with another clear coat containing the chlorinated component, along  
15 with the plasticizers and heat and light stabilizers mentioned above. For instance, FIG. 2  
illustrates an alternative embodiment in which a PVC-containing clear coat 41 is substituted  
for a color coat as described above. In this embodiment, one or more separate optional ink  
layers 42 bonded to the second clear coat 41 can provide the necessary coloration and opacity.  
The ink layers suitable for use in this invention are described in more detail below.

#### Pressure-Sensitive Adhesive Coat

20 Referring again to FIG. 1, the adhesive layer 18 is next laminated to the dried color  
coat. The adhesive layer is coated on the second carrier sheet 20 and dried on the carrier  
before laminating the dried adhesive coat to the color coat. The adhesive coat is dried in  
25 ovens similar to those used to dry the clear coat and color coat, but at much lower  
temperatures. The adhesive coat bonds the paint coat to the exterior automotive substrate in  
the application step described below. The adhesive coat preferably comprises an acrylic-based  
synthetic resinous material which is activated from pressure applied during the subsequent  
application step to bond the paint coat to the exterior automotive substrate. The preferred dry  
30 film thickness of the adhesive coat is from about one mil to about 1.5 mils.

The pressure sensitive adhesive is preferably cast on a smooth surfaced polyester  
casting sheet in a separate operation. The adhesive coat is dried to produce a smooth surface.  
The adhesive coat is then laminated to the PVC color coat side of the paint layer composite  
to provide the adhesive backing. Any surface roughness of the adhesive coat can be reflected  
35 through the top coat of the finished paint coated laminate, thereby reducing DOI of the  
finished product. Casting the adhesive in a separate step on a smooth polyester carrier  
produces a sufficiently smooth surface that DOI of the finished product is not significantly

1 affected when laminating the pressure-sensitive adhesive to the paint coated laminated. The adhesive coat is not cast directly on the dried PVC coat to avoid the adhesive solvents from attacking the PVC coat.

5 **Application Procedures**

For vehicle preparation, all areas of the car body panel are thoroughly washed to remove all factory applied protective coatings. Surfaces must be smooth and free from paint defects such as pits, paint nibs, dirt, sags, and rough two-tone paint break lines. These defects are removed by sanding, and using 360 or 400 grit wet or dry sandpaper. Such defects can telescope through the film if not removed.

10 The cleaning procedure involves using a clean, lint-free cloth to wipe the areas with naphtha cleaner. Next, a second clean, lint-free cloth, is used to wipe the areas with isopropanol. Then, using a third clean, lint-free cloth, the entire area is dry-wiped. The film should be applied as soon as reasonably possible after the dry-wipe step to avoid additional contamination.

15 Temperature effects can have a profound effect on application properties. Film application is most easily made when air, film and body surface temperatures are between 21° C and 32° C. For applications below 21° C, heat lamps or other suitable means are used to warm the body surface and film. The body surface must be allowed to cool if above 32° C. The film should not be applied when the film and surface temperature are below 15° C.

20 Tools and equipment include plastic squeegee (both with and without a felt oversleeve), spray bottle, air release tool or pin, razor blades, heat gun, clean, lint-free cloths, heaters, naphtha, isopropanol, detergent or surfactant, and 360 and 400 grit wet/dry sandpaper.

25 Since contamination can be visible in the film application, the working area should be draft free and free from dust or dirt. Lighting should be bright enough to clearly reveal all vehicle contour lines without shadowing, especially in the lower body area. Heat lamps should be available when lower temperatures are expected.

30 The first step in the application procedure is removal of the polyester carrier or liner 20 covering the adhesive layer 18. During the liner removal step, the film is placed on a clean, flat surface with the liner side up. The liner is removed in a smooth, 180° motion. It is mandatory to remove the liner from the film, and not vice versa, since removing the film from the liner can cause film stretching.

35 After the liner has been removed, the adhesive side of the film and the car body surface are moistened with a solution of 2.5 ml of detergent or surfactant per liter of deionized water. More detergent or surfactant may be added if temperature and humidity are high. Wetting the surface in this manner temporarily lowers the aggressiveness of the adhesive, which facilitates positioning of the film and later removal of any air bubbles or wrinkles. The film

-16-

1 is next aligned to the proper location on the car body panel. Starting in the center and working outward, a squeegee is used to pressurize the film to the surface with firm, overlapping strokes, making sure accurate alignment is maintained. Squeegeeing is repeated until all water and air are removed from beneath the film and proper edge bonding is ensured.

5 The first carrier sheet 10 has been replaced by a pre-mask which is removed by pulling it back over itself in a smooth, steady motion at a 180° angle. (In some instances the first carrier sheet can be left in place in which case the pre-mask is not used.) The applied film is inspected for air bubbles which are pierced with an air release tool or pin. The squeegee is used to force air and water out through the pierced hole. If trimming the film is necessary, 10 a sharp razor blade with a back-up template are used to prevent damage to any painted areas. The entire surface of the film is examined for manufacturing flaws, wrinkles, or misalignment. The entire surface of the film is resqueegeed, using the squeegee with a felt oversleeve, to ensure that all edges have received adequate pressure to prevent tape peeling.

15 **Characteristics of Finished Paint Coat**

The following are physical properties used herein to measure whether the finished paint coat is useful as an exterior automotive paint coat:

- (1) Gloss
- (2) Distinctness-of-Image
- 20 (3) Color Uniformity (hiding ability)
- (4) Dry Film Thickness Uniformity
- (5) Gasoline Resistance
- (6) Solvent Resistance
- (7) Acid Spotting Resistance
- 25 (8) Hardness
- (9) Abrasion Resistance
- (10) Adhesion of Paint Coat
- (11) Accelerated UV Resistance
- (12) Resistance to Water and Humidity Exposure
- 30 (13) Intercoat Adhesion
- (14) Peel Adhesion
- (15) Tensile Strength and Elongation
- (16) Volatile Haze

35 Properties (1) through (4) are considered appearance properties and properties (5) through (15) are considered durability properties. Specifications and tests methods for each of these physical properties are described below. Certain specifications and test methods

1 identified below are defined by publicly available industry specifications and test methods  
which are incorporated herein by this reference.

5 (1) Gloss is measured by specular reflectance of a beam of light at angles of 20,  
60, and 85 degrees. The desired specular reflectance for an exterior automotive paint coat  
surface is at least about 60 to 65 gloss units at 20 degrees, and at least about 75 to 80 gloss  
units at 60 degrees. The 85 degree gloss reading may be used for low gloss measurements.  
Specular reflectance and other criteria herein are measured before the finished painted  
surface is buffed and waxed. A preferred test method is described in GM Test Specification  
10 TM-204-A. The Byk-Mallinckrodt "multigloss" or "single gloss" gloss meters can be used  
for measuring specular gloss of the finished surface. Those gloss meters give values  
equivalent to those obtained from ASTM Method D-523-57. Either gloss meter is used with  
gloss standards covering the expected range of measurement, together with a piece of polished  
black glass plate of known refractive index. The gloss meter is calibrated by setting it to read  
the gloss of a highly polished standard and then reading the gloss of a working standard  
15 having a value preferably in the range of the test panel. The second standard should agree  
within one unit of its assigned value. At least two readings are taken on a different area of  
the test panel. These values are averaged if they agree within one unit. If the range is larger  
than one unit, additional regions are taken and a mean value is calculated.

20 (2) Distinctness-of-Image (DOI) is a measurement of the clarity of an image  
reflected by the finished surface. DOI can be measured from the angle of reflection of a light  
beam from a spherical surface. The desired DOI for an exterior automotive paint coat surface  
is at least about 60 units, where 100 units is the maximum DOI reading. DOI is measured  
by the Hunterlab Model No. D47R-6F Dorigon Gloss Meter. A test panel is placed on the  
instrument sensor and the sharpness of the reflected image is measured. Details of the DOI  
25 test procedure are described in GM Test Specification TM-204-M, which are incorporated  
herein by reference.

30 (3) Color uniformity is a test to determine whether coloration of the paint coat  
remains uniform after application. Coloration is tested after the paint coat is coated on the  
casting sheet. Coloration testing is repeated after a deep draw stretch simulating elongation  
during application, to determine whether the color has changed. A desirable coloration  
uniformity can be a color change of no greater than about one to two McAdam units on a  
colorimeter.

35 (4) Dry Film Thickness (DFT) is a standard industry measurement of the film  
thickness of the finished paint coat, to determine whether the paint coat thickness matches a  
required film thickness specified by the auto manufacturer. For the present exterior  
automotive specifications, uniformity of the finished paint coat is determined to be a more  
useful parameter in determining whether the paint coat meets appearance requirements.

1 Thickness uniformity of the finished paint coat can be measured from several locations on the finished article, including highly contoured areas, to determine whether variations in the thickness of the finished paint coat exceed a desired level.

5 (5) Gasoline Resistance requires no color change, degradation, tackiness, marring or loss of paint adhesion on plastic parts used on and adjacent to fuel filler openings after being immersed for ten seconds, ten times, in a specified reference fuel with a 20 second dry off period between each immersion. Immediately after the tenth immersion, the painted surface is checked and must pass Thumbnail Hardness according to GM Test Specification TM 55-6, incorporated herein by reference.

10 (6) Cleanability is tested according to GM Test Specification TM 31-11 which is incorporated herein by reference. According to this test, the painted plastic part is required to withstand ten rubs with cheesecloth saturated with 9981062 Naphtha or currently used and approved cleaning solvents, with no evidence of staining, discoloration, or softening of the painted surface. This test requires no evidence of color transfer from the test part of the cloth. One rub consists of one forward and backward motion.

15 (7) Acid Spotting Resistance requires the test part to withstand exposure to 0.1 N sulfuric acid for 16 hours without any evidence of staining, discoloration, or softening of the painted surface.

20 (8) Hardness is measured by a standard Knoop Hardness Test. The required hardness is at least a Knoop hardness number of four.

25 (9) Abrasion Resistance is tested by a gravelometer under the standard test method identified as SAE J-400. According to this test, the painted part shall withstand the Gravelometer Test at minus 30°F with a minimum rating of eight (F.B. Gravelometer Rating Chart). The tested part should withstand the Gravelometer Test as received and after Florida exposure described below. A Fisher Body Material Specification FBMS 26-7 (incorporated herein by reference) also defines a minimum level of wear resistance for the finished paint coat.

30 (10) Paint adhesion is tested by a standard Tape Adhesion Test described in GM Test Specification TM 55-3, which is incorporated herein by reference. According to this test, a tape is pressed down over an X-shaped cut in the paint coat and the tape is then removed to test the amount of peeling. The Adhesion Test requires a minimum of 99% of the paint remaining in the tape test area.

35 (11) Accelerated UV Resistance, also referred to as Accelerated Weathering, measures the weatherability of a paint coat in accelerated test procedures designed to provide an accurate indication of long-term UV resistance or other weatherability properties. The two methods used to measure accelerated UV resistance are QUV and Xenon Weatherometer. According to a QUV test useful for measuring accelerated UV resistance, the test panel

1 should not show any significant surface deterioration or embrittlement, loss of coating  
adhesion, objectionable shrinkage, or noticeable color or gloss change after about 2000 hours  
exposure to UV light and condensation apparatus per ASTM G-53 using eight hour UV cycle  
at 70°C and four hour humidity cycle at 50°C. A panel tested in the Xenon Weatherometer  
5 should exhibit the same characteristics as a panel that successfully passes the QUV test. The  
xenon specification used was SAE J1960, with 2500 hours as the exposure period.

(12) Resistance to Water and Humidity Exposure is measured by several tests.  
According to a first test, the finished part shall withstand 96 hours of humidity exposure at  
100% relative humidity and 100°F in a humidity cabinet defined in GM Test Specification  
10 TM 55-3, and a two-hour water immersion test of 100°F according to GM Test Specification  
TM 55-12. These test specifications are incorporated herein by reference. The resulting test  
panel should show no evidence of blistering when examined one minute after removal from  
the test cabinet and shall withstand the Paint Adhesion Test described above. The Paint  
Adhesion Test is performed within one minute after removal from either test cabinet. In a  
15 second test, the finished part should withstand 15 cycles of the Moisture-Cold Cycle Test  
defined in GM Test Specification TM 45-61A (incorporated herein by reference), without any  
visible signs of cracking or blistering. After 15 cycles, the part shall withstand 96 hours of  
the humidity exposure described above, followed by passing the Paint Adhesion Test also  
described above. The Paint Adhesion Test is performed within one minute after removal  
20 from the humidity environment. One cycle consists of 24 hours and 100% relative humidity  
at 100°F, 20 hours at minus 10°F, and four hours at room temperature.

(13) Intercoat Adhesion is tested in the same manner as in (10), except that the bond  
between the clear coat and color coat is being gauged, instead of the adhesive bond to the  
automotive substrate. In this test, the GM Test Specification TM 55-3 is again used, except  
25 that the cut made is only down to the surface of the color coat, not all the way through to the  
substrate. Tape is pressed down over the X-shaped cut and the tape is then removed to test  
the amount of film anchorage. If the paint coat passes this initial test, it is placed in a water  
bath at 70°C. The paint coat is then removed periodically from the water bath (usually every  
day), allowed to dry, and the tape test is repeated. The test is considered a failure when the  
30 clear coat separates from the color coat.

(14) Peel Adhesion is a test used to measure the strength of the adhesive bond  
between the paint coat and the automotive substrate. The test is performed according to the  
ASTM D3330 specification. Usually peel adhesions are measured initially (immediately after  
application), and after a variety of exposure conditions, such as humidity, salt spray,  
35 environmental paint cycles, and QUV.

(15) Tensile Strength and Elongation are tests used to: (1) Measure the force  
required to stretch a sample of the paint coat until it breaks, and (2) Measure how much the

-20-

1 film has elongated at the instant it breaks. The tests are run according to the ASTM D3759  
specification. Tensile Strength and Elongation are usually run initially and after various  
exposure conditions, especially heat aging. These two tests measure properties that are very  
important in the application of the paint coat, since the paint coat must have enough strength  
5 to prevent breakage when it is elongated, and must have sufficient elongation to be stretched  
for application to complex three-dimensional shapes.

(16) Volatile Haze is a non-standard test which the applicant uses to measure the  
presence of components, especially plasticizers, which migrate to the surface of the film  
during a heat test. This heat test involves placing test panels in an 80°C air circulating oven  
10 for a period of two weeks. During this time, the test panels are removed from the oven daily  
and inspected for haze; the haze usually appears as a white substance which can be wiped off  
the surface of the film. Besides the visual inspection, haze can also be detected by measuring  
the gloss of the film, as described in Gloss Test (1) described above. A gloss decrease of  
greater than 25% over the two week period is an indication that haze is present. If gloss  
15 decrease measures greater than 25%, the result is considered a test failure.

#### EXAMPLE 1

A high gloss black exterior automotive paint coat was applied to the exterior surface  
of an automobile body panel. The panel was a sheet metal body panel having a flat outer  
20 surface. The paint coat was first coated onto a surface of a flexible polyester film casting  
sheet. The flexible carrier comprised two mil thick high gloss Hoechst Celanese 3900  
polyester film. The paint coat comprised a clear coat, a tie coat, a color coat and an adhesive  
coat, in that order, similar to the construction shown in FIG. 1.

The clear coat was prepared from the following formulation:

<u>Ingredient</u>	<u>Parts</u>
N-Methyl-2-pyrrolidone (M-Pyrol)	54.00
Polyethyl Methacrylate (Elvacite 2042)	6.30
PVDF (Kynar 301F)	11.70
UV Absorber (Tinuvin 234)	0.36
Methyl Ethyl Ketone (MEK)	27.64

30 The M-Pyrol is a solvent available from GAF Corp. Tinuvin is a trademark for a  
family of UV absorbers available from Ciba-Geigy Corp. The Kynar and Elvacite resins are  
described above.

35 The PVDF, acrylic resin and UV absorber were dissolved. The Elvacite 2042, Kynar  
301F, and Tinuvin 234 were dissolved in the M-Pyrol under high speed agitation. The  
mixture was allowed to heat to no greater than 130°F, then allowed to cool before the MEK  
solvent was added. The viscosity was adjusted to 1100 centipoise, using M-Pyrol as the  
thinner.

1 The clear coat was coated on the polyester casting sheet in a dry film thickness of about 0.8 mil. The clear coat was applied to the sheet by a reverse roll coater (illustrated in FIG. 6). The clear coat was dried on the carrier sheet by passing it through a multi-zone impinging air drying oven having three heating zones spaced apart axially along the length 5 of the carrier, with each drying zone having a progressively higher temperature. The clear-coated carrier was passed through the heating zones at a line speed of 25 feet per minute and each heating zone was 40 feet long. Temperatures of the three heating zones were: Zone 1: 240°F, Zone 2: 300°F, Zone 3: 350°F. Passing the clear coat through the three heating zones removed substantially all solvent gases from the clear coat to produce a dry clear coat 10 of uniform film thickness. The dried clear coat comprised approximately 65% PVDF and approximately 35% acrylic resin, by weight of the total PVDF and acrylic solids.

A clear acrylic-based tie coat was next coated on the dried clear coat at a dry film thickness of about 0.1 mil. The tie coat formulation was as follows:

<u>Ingredient</u>	<u>Parts</u>
Toluene	40.00
N-Propyl Acetate	39.70
UV Absorber (Tinuvin 234)	0.30
Polyethyl Methacrylate (Elvacite 2042)	20.00

15 The Tinuvin 234 and Elvacite 2042 were dissolved in the toluene and N-Propyl Acetate under high speed agitation. The viscosity was adjusted to 300 cps using toluene as the thinner. 20

The tie coat was applied to the dried clear coat on the casting sheet by means of a 137 HK gravure cylinder, at a line speed of 100 feet per minute. The tie coat was passed through one oven zone at 200°F.

25 The color coat was then prepared from the following formulation:

<u>Ingredient</u>	<u>Parts</u>
Aromatic Solvent (Hi-Sol 10)	19.39
2-Ethyl Hexyl Acetate	6.46
UV Absorber (UV 531)	1.96
BaZn Heat Stabilizer (MK 2181)	2.93
Epoxy Heat Stabilizer (TC 909)	1.93
Acrylic Copolymer (B 99)	2.44
Plasticizer (C.P. Hall G-59)	3.91
Polyvinyl Chloride (Geon 199)	48.82
Black Dispersion	12.14

30 The Hi-Sol 10 is an aromatic petroleum distillate, available from Ashland Chemical Co. The black dispersion comprised 15% carbon black pigment and 35% Hi-Sol 10 in a vehicle of Emery 9776, available commercially as Universal Color Dispersions UCD-26776. The acrylic copolymer comprised 50% acrylic resin, 35% xylene and 15% toluene and is available as product no. B 99 from Rohm and Haas. The epoxy heat stabilizer is a proprietary epoxy 35

1 resin, product name Therm-Chek 909, available from Ferro Corporation. The BaZn heat  
stabilizer is an organo barium zinc heat stabilizer, product name Mark 2181, available from  
Witco Corp. The UV absorber has a product name Cyasorb UV 531, available from  
5 Cyanimid Corp. The plasticizer is a poly (1, 2-propylene glycol adipate)-polymeric  
plasticizer, product no. G-59, available from C.P. Hall Corp.

The color coat was prepared by first mixing the Hi-Sol 10 and 2-Ethyl hexyl acetate.  
Next, the UV 531, MK 2181, TC 909, B 99, and the plasticizer were added under low  
agitation. The Geon 199 was then added under high agitation and mixed until it was observed  
10 that no solid particles remained in the solution. The black dispersion was then added under  
low agitation. On a weight basis, the amount of pigment contained in the color coat  
formulation was about 1.2%. The total solids of the wet solution was 71.8%.

The black PVC-based color coat was coated on the dried tie coat layer to a dry film  
thickness of about 2.2 mils. The color coat was applied to the sheet by the same reverse roll  
coater that was used for the clear coat. The line speed was 25 feet per minute. Temperatures  
15 of the three heating zones were: Zone 1: 160°F, Zone 2: 270°F, Zone 3: 360°F. Passing  
the color coat through the three heating zones removed substantially all the solvent to produce  
a dry coat of uniform film thickness.

The acrylic-based pressure sensitive adhesive was next prepared. This adhesive is  
available commercially as Monsanto 2591. The adhesive, which is a self-crosslinking system,  
20 consists of approximately 36% acrylic resin solids, with the remainder being a mixture of  
solvents, namely, toluene, ethyl acetate, and isopropanol.

The adhesive was reverse roll coated on a separate silicone coated polyester film  
casting sheet. The flexible carrier comprised two mil thick ultra-smooth H.P. Smith 2094  
polyester film. The adhesive was dried at a line speed of 45 feet per minute. The final dry  
25 film thickness was about 1.2 mils. A three heating zone oven was again used, with the  
following zone temperatures: Zone 1: 140°F, Zone 2: 180°F, Zone 3: 200°F. Passing the  
adhesive through these three heating zones was sufficient to remove 99% of the solvents from  
the adhesive.

After the dried adhesive had exited the last oven zone, it was passed over a chill roll,  
30 and was then laminated to the PVC side of the paint coat in an operation illustrated in FIG.  
7. In the laminating step, the paint-coated carrier 10, which includes the clear coat and color  
coat, is stored on a top unwind roll 50. The adhesive-coated carrier 12, in flat form, is  
shown at 52. The paint-coated sheet is passed around a drum 54, and the adhesive-coated  
carrier 52 is passed around a drum 56 spaced from the drum 54. The paint-coated carrier  
35 10 and adhesive-coated sheet 20 then pass between a laminating drum 58 and a rubber  
back-up roll 60 for pressing the two sheets into contact to bond the adhesive layer to the color  
coat. Following the laminating step, the flexible paint-coated adhesive-backed laminate, with

1 the carrier sheets 10 and 20 acting as outer liners on both sides of the laminate, is then passed around a roll 62 and onto a laminate rewind drum 64.

5 The adhesive coated construction was then sheeted and die cut to the desired shape. The sheeting operation occurs after the laminate has been unwound from the rewind drum 64. The top polyester liner (originally used for casting of the clear coat) was stripped away and replaced by an exterior automotive application tape (commonly known as a pre-mask), commercially available as American Biltrite X758. Before application, the bottom polyester liner (originally used for adhesive casting) was removed to expose the adhesive. The adhesive-coated side of the construction was applied to the automotive substrate. When the construction was positioned correctly, a squeegee was used to apply pressure, after which the pre-mask was removed.

10 The exterior automotive substrate was tested and the tests demonstrated the usefulness of the paint coat as an exterior automotive paint coat. The test results indicated that desirable appearance properties, including gloss and DOI, were produced. Gloss measured 70 units at 20 degrees. DOI measured 90%. The test panel passed gasoline resistance, acid resistance, abrasion resistance, impact resistance, QUV and humidity, and paint cycle exposure tests, according to test methods similar to those described above. A Volatile Haze test, as described above, revealed haze problems. Changes in the plasticizer formulation improved haze resistance as described in Example 4.

## 20 EXAMPLE 2

This series of tests studied the effects of several factors simultaneously, including: (1) The ratio of PVDF to polyethyl methacrylate in the clear coat; (2) The addition of a PVDF copolymer into the clear coat, where the copolymer replaced part of the PVDF polymer normally used; (3) The fusion temperature used for the clear coat; (4) The UV absorber level in the clear coat; (5) Post-process heat treating of the paint coat in which the finished paint coat is heated in a convection oven at 150° - 170° C for ten minutes; (6) The method of application of the PVC color coat to the tie coat/clear coat (the usual method was to cast the PVC color coat to the tie coat/clear coat; the alternative was to cast the PVC by itself and laminate it to the tie coat); (7) Applying one or two coats of PVC; (8) The type of polyethyl methacrylate used in the clear coat; and (9) The level of plasticizer in the PVC color coat.

Each of these factors was studied at two levels in an orthogonal array of 16 experiments and included each of the factors at one of the two levels.

The following table shows the factors tested at each of the two levels.

-24-

1	<u>Factor</u>	<u>Level 1</u>	<u>Level 2</u>	<u>Manufacturer</u>
	PVDF/PEMA ratio	72:28	65:35	PVDF (301F)- Atochem PEMA (2042)- DuPont
5	Copolymer level	0 phr	5 phr	PVDF (10052)- Atochem
	Fusion temp.	350°F	370°F	-
	UV absorber level	1 phr	3 phr	Tinuvin 234- Ciba Geigy
10	Post-Process Heat Treating	yes	no	-
	PVC Application Method (lamination) (direct coat)	cold	hot	-
15	1 or 2 coats PVC	1 coat	2 coats	-
	EMA type	2042	2659	DuPont (for both)
	PVC Plasticizer Level	20 phr	35 phr	Two plasti- cizers used in combination: G-59 (C.P.Hall) EM 9776 (Emery)
20				

25 Each of the 16 experimental constructions was prepared and cast by methods described in Example 1, but in a laboratory setting. After the constructions were made, they were subjected to a variety of tests, for which a response was measured for each test. For instance, one of the tests involved the Volatile Haze test. Another measured response was the amount of intercoat adhesion between the clear coat and color coat, using a tape adhesion test. Additional properties tested were the tensile strength and elongation of the constructions.

30 The level averages for each factor were calculated, for each of the responses measured. For the gloss decrease response, the only factor which had any significant effect was (5), the post process heat treating of the paint coat. This led to the conclusion that post process heat treating could greatly reduce the amount of gloss decrease recorded in the Volatile Haze test.

35 For the intercoat adhesion response, the only significant factor was (6), the method of application of the PVC color coat. It was found that casting the PVC color coat separately and then laminating the clear coat to the color coat led to a high occurrence of intercoat adhesion failure. This confirmed that the best method of application was to cast the PVC color coat directly onto the tie coat.

**EXAMPLE 3**

Another set of experiments studied the paint coat by investigating the following factors: (1) Clear coat film thickness, (2) Tie coat thickness, (3) PVC plasticizer level, (4) PVC fusion temperature, and (5) PVC color coat film thickness. An array of 16 experimental samples were prepared in a manner similar to that described in Example 1, except for the second factor, tie coat thickness, in which the larger thicknesses of tie coat were applied with a Mayer rod, instead of the 137 HK gravure process.

Responses were measured, including room temperature elongation, tensile strength, shrinkage, and volatile haze factor. Responses showed that higher clear coat and color coat thicknesses produced better tensile strength and elongation; that shrinkage was minimized by reducing the thicknesses of the clear coat, tie coat, and PVC color coat; that having a high PVC level increases elongation but decreases tensile strength of the finished paint coat; and that a PVC fusion temperature between the highest and lowest levels produces the best elongation. The plasticizer used in the PVC layer affects elongation, as well as tensile strength; volatile haze also can be affected by the particular plasticizer used.

It was concluded as follows: (1) The topcoat (clear coat) film thickness did not have a significant effect on overall results; (2) The tie coat thickness can remain at one gravure pass; better elongation, lower shrinkage, and less volatile haze were the deciding factors; (3) PVC plasticizer should be kept between 26 and 35 phr (parts per 100 PVC resin); this range gave the best results for shrinkage and elongation; (4) PVC fusion temperature should be kept at or below 184°C; the lower elongation values recorded at 199°C indicate that the paint coat may absorb too much heat at this higher temperature, causing brittleness; (5) PVC film thickness was determined to be best at 2.0-2.5 mils; although a greater thickness would produce better tensile and elongation, these improvements could not be justified because of the greater cost.

**EXAMPLE 4**

One of the problems experienced with the paint coat of Examples 1-3 was plasticizer migration from the PVC-based color coat to the surface of the clear coat when the film becomes heated. The plasticizer appears as a haze on the surface of the film, which decreases gloss.

To solve this problem, an experiment was conducted to determine whether a different plasticizer could eliminate or reduce the haze. The following PVC formula was used as a base:

-26-

1	<u>Ingredient</u>	<u>Parts</u>
	Aromatic Solvent (Hi-Sol 10)	15.42
	2-Ethyl Hexyl Acetate	6.43
	UV Absorber (UV 531)	2.06
	BaZn Heat Stabilizer (MK 2181)	3.08
5	Epoxy Heat Stabilizer(TC 909)	2.06
	Acrylic Copolymer (B 99)	2.57
	Polyvinyl Chloride (Geon 199)	51.41
	Plasticizer	16.97

Eight different plasticizers were substituted in the above formula, including EM-9776, EM-9789, EM-9790 (from Emery Corporation), PLR-100 (from Huls America), and G-25, G-59, P-670, and P-1070 (from C.P. Hall Corporation). At the time this experiment was conducted, the EM-9776 and G-59 were the plasticizers used in the PVC color coat formula.

The eight formulas were prepared and cast in methods similar to those used in Examples 1-3. The eight formulas were laminated to test panels, and the initial 20 degree gloss was measured. An "X" was also scribed in the surface of the film, so that the shrinkage could be measured. The panels were then heat aged for 24 hours at 70°C. (This time and temperature were sufficient to cause the plasticizer to migrate, and this test was considered a reasonable substitute for the usual Volatile Haze test run at 80° for two weeks.) At the end of 24 hours, the gloss was again recorded, along with the shrinkage, with the following results:

20	<u>Plasticizer</u>	<u>Initial 20° Gloss</u>	<u>Final 20° Gloss</u>	<u>Shrinkage (mils)</u>
	EM-9776	60	22	37
	EM-9789	58	47	11
	EM-9790	60	49	11
	G-25	58	53	5
	G-59	58	25	33
25	PLR-100	61	17	43
	P-670	60	33	27
	P-1070	60	13	47

These results showed that the G-25, EM-9789, and EM-9790 had the best gloss retention (gloss retention for 20° gloss was within 20% of its initial gloss measurement) and also had the lowest shrinkage. However, the G-25 had the disadvantage of having a very high viscosity which made compounding difficult. The EM-9790 was more convenient to use primarily because of its lower viscosity. On the basis of this experiment, the plasticizer system in the PVC color coat was changed from the G-59/EM-9776 to the EM-9789/EM-9790. This plasticizer system comprised polyester azelates (propylene glycol azelaic acids) having molecular weights (number average) of 7,080. When the paint coat containing the Emery 9789/Emery 9790 system was subjected to the Volatile Haze test, it was found that gloss retention after heat aging was sufficient to eliminate the need for post-process heat treating described in Example 2.

**EXAMPLE 5**

As the result of several designs of experiments, it was possible to construct a formulation which provided the best overall combination of properties. This formulation was tested in the PVC color coat, using a variety of pigments, including white, pearlescent, metallic, and clear (non-pigmented). These PVC color coats were prepared from the following base formula, to which the particular pigments were later added:

<u>Ingredient</u>	<u>Parts</u>
Aromatic Solvent (Hi-Sol 10)	22.84
2-Ethyl Hexyl Acetate	7.59
UV Absorber (UV 531)	4.07
CaZn Heat Stabilizer (MK 4119)	3.49
Epoxy Heat Stabilizer (TC 909)	2.33
Acrylic Copolymer (B 99)	1.46
Polyvinyl Chloride (Geon 199)	58.22

This color coat formulation was used in combination with the PVDF-acrylic outer clear coat and the tie coat of Example 1.

As to the pigmented formulations, it was found that the EM 9789/EM 9790 plasticizer combination (with the EM 9790 used in the pigment dispersions, and the EM 9789 used to adjust the plasticizer level, if necessary) was the optimum plasticizer system. It was also found that the best combination of properties was obtained when the plasticizer-to-PVC resin ratio was set at 36 parts plasticizer to 100 parts PVC resin.

When the above base formulation was used as part of several pigmented PVC-based color coats, it was found that superior results were achieved in a number of tests, including: intercoat adhesion, accelerated UV resistance, shrinkage resistance, resistance to plasticizer migration, and gloss retention.

**EXAMPLE 6**

Tests were conducted to determine whether the PVDF-acrylic clear coat could be bonded to the PVC color coat without the use of a tie coat. The coating procedure followed was similar to that described in Example 1, except that the tie coat formulation and casting steps were omitted. The formulas for the clear coat, color coat, and adhesive were also similar to those in Example 1. The resulting construction is illustrated in FIG. 3.

Several tests were run on this construction, including initial peel adhesion, initial intercoat adhesion, water immersion, humidity, QUV, and Xenon Weatherometer. The initial peel and intercoat adhesion results were similar to those achieved with the construction containing the tie coat. After 96 hours of humidity exposure, the construction passed the tape test. After nearly 1500 hours in the QUV and 2000 hours in the xenon weatherometer exposure, signs of intercoat adhesion failure began to appear; specifically, the clear coat

-28-

1 began to separate from the color coat. When these same samples were removed from the exposure cabinets, allowed to dry, and were subjected to the tape test, the intercoat adhesion failure was complete.

5 This result indicated that absence of the tie coat eventually led to intercoat adhesion failure in this test.

The same construction having a tie coat 14 passed the same tests. Thus, it was concluded that a tie coat is necessary to improve interlayer adhesion between a PVDF-acrylic based clear coat and a PVC-containing color coat.

#### 10 EXAMPLE 7

This experiment was conducted to determine whether the clear coat could be used as a protective layer in place of a two-package urethane that is often used as a protective layer for screen printed PVC films. This approach could provide some advantages to a screen printing converter. For example, the adhesive coated clear coat is available as a continuous sheet, as opposed to the two-package urethane, which is applied in a batch process one sheet at a time. This would allow screen printed PVC sheets to be continuously fed into a laminator. Also, since the clear coat is already a finished film, there would be no need to dry each sheet individually, as is necessary with a two-package urethane.

20 Referring to FIG. 4, the clear coat 12 was prepared and coated in a method similar to that described in Example 1, except that the clear coat was cast on a silicone coated paper carrier. An adhesive layer 44 was also prepared by a method similar to the adhesive 14 in Example 1, except that the adhesive was cast on a silicone coated paper carrier and directly laminated to the clear coat after the adhesive exited the drying oven, as illustrated in FIG. 7. The adhesive layer 44 had a dry film thickness of about 1.2 mils.

25 For this experiment, the PVC color coat 16 contained a white pigment prepared from the following formulation:

<u>Ingredient</u>	<u>Parts</u>
Aromatic Solvent (Hi-Sol 10)	15.03
2-Ethyl Hexyl Acetate	5.00
UV Absorber (UV 531)	1.52
30 BaZn Heat Stabilizer (MK2181)	2.27
Epoxy Heat Stabilizer (TC909)	1.51
Acrylic Copolymer (B 99)	1.89
Plasticizer (Emery 9789)	2.01
Polyvinyl Chloride (Geon 199)	37.84
White Dispersion	32.93

35 The white dispersion comprised 59.1% Du Pont R960 white pigment and 9.1% Hi-Sol 10 in a vehicle of Emery 9790, available commercially as Harwick HCC-9978. The color coat was prepared by a procedure similar to that of the black color coat of Example 1. On

1 a weight basis, the amount of pigment contained in the color coat formulation was about 19.5%. The total solids of the wet solution was 76.0%.

5 The white PVC-based color coat was coated directly onto a silicon coated paper liner available as H. P. Smith 8227. The film was cast to a dry film thickness of 2.2 mils. The line speeds and zone temperatures were similar to those used for the black PVC color coat of Example 1.

10 Referring again to FIG. 4, in an adhesive casting step, an acrylic-based pressure sensitive adhesive 46 was separately cast and dried and then laminated to the PVC color coat 16 as described in Example 1. The PVC color coat/adhesive construction was unwound from the roll and sheeted. One of these sheets was screen printed with five different colored acrylic-based inks, forming a composite ink layer 48. The inks were obtained from the Sinclair-Valentine Company. The screen printed material was dried in a convection oven for one hour at 160°F.

15 After the ink was dried, the screen printed sheet was allowed to cool to room temperature. The liner was then stripped from the adhesive coated side of the clear coat film, and the adhesive coated clear coat was pressure laminated to the screen printed side of the PVC sheet.

20 This construction was cut into several pieces and laminated to automotive test substrate panels. Initial gloss and distinctness-of-image readings were taken. Gloss measured 70 units at 20 degrees. DOI measured 30. The gloss reading was judged comparable to other paint coat constructions, but the DOI was much lower. The lower DOI was attributed to the adhesive layer between the screen printed ink layer and the clear coat and also because the adhesive was coated on a paper carrier sheet. Several other tests were run, including peel adhesions, intercoat adhesion, humidity, QUV, and xenon weatherometer. The construction showed good results for the adhesion and humidity tests. After 2000 hours QUV and xenon tests, the construction started to show a slight intercoat adhesion failure after the tape test.

25 The slight intercoat adhesion failure showed that an improvement was needed in the adhesive layer connecting the clear coat to the screen printed ink layer.

### 30 Example 8

35 A paint coated laminate was formed as shown in FIG. 5. This construction included a PVDF-acrylic color coat 50 formed between the PVDF-acrylic clear coat 12 and the PVC color coat 16. A grain coat 52 made with multiple ink layers was formed between the PVDF-acrylic clear coat 12 and the PVDF-acrylic color coat 50. The grain coat, which is printed by a gravure process, produces an extra visual effect. The grain coat can provide a variety of patterns, such as a woodgrain, which requires multiple gravure coats. The tie coat 14 was used for bonding the PVC-containing color coat 16 to the PVDF-acrylic color coat 50. This

1 construction was tested to determine whether it provided better elongation and weathering resistance than a construction without the PVDF-acrylic color coat 50.

The construction was made by first preparing the PVDF-acrylic clear coat 12, which had the same formulation as in Example 1, and was compounded, coated, and dried in the same manner also as in Example 1.

Next the grain coat was prepared by first making an intermediate formulation as follows:

<u>Ingredient</u>	<u>Parts</u>
Methyl Ethyl Ketone (MEK)	41.54
Elvacite 2010	4.15
Kynar 7201	12.45
Tinuvin 234	0.33
Methyl Propyl Ketone (MPK)	41.53

The Elvacite 2010 was added to the MEK under high agitation, followed by the Kynar 7201 and Tinuvin 234. This mixture was allowed to heat to 130°F to dissolve the resins. The MPK was then added and the mixing container was weighed. MEK was then added to make up for the solvent lost during mixing, to form the finished intermediate formulations.

The grain coat was next prepared from the following formulation:

<u>Ingredient</u>	<u>Parts</u>
Intermediate	84.07
Methyl Propyl Ketone (MPK)	12.79
93 QA Violet (DP 37100)	0.92
93 Carbon Black (DP 39100)	1.70
93 IR Blue (DP 34200)	0.52

The DP dispersions consist of pigment in a vehicle of Rohm and Haas B735 acrylic resin, available commercially from the Gibraltar Chemical Co.

The grain coat was prepared by adding the MPK to the intermediate formulation, and then adding the DP dispersions under low agitation.

The grain coat was applied to the clear coat at the same thickness, line speed, gravure cylinder, and oven conditions as the tie coat in Example 1.

The PVDF-acrylic color coat was prepared from the following formulations.

<u>Ingredient</u>	<u>Parts</u>
n-Propyl Acetate (NPAC)	62.95
Elvacite 2043	12.35
Kynar 9301	12.35
Aluminum flake (L 54894)	12.35

The L 54894 consisted of aluminum flake dispersed in isopropyl acetate, and is available commercially from Avery-Dennison. This color coat was prepared by adding the Elvacite 2043 and Kynar 9301 to the NPAC and mixing under high agitation. After the resins were completely dissolved, the L 54894 was added and mixed under low agitation.

1           The PVDF-acrylic color coat was coated and dried under the same conditions as the PVDF-acrylic clear coat.

5           At this point, a portion of the construction was set aside for future testing. This was done so that a comparison could later be made between the construction both with and without the PVC color coat.

          The acrylic-based tie coat was prepared by the same procedures as in Example 1.

          The final coating to be cast was the PVC color coat, which was a white color coat with the same formulate as in Example 3. It was processed at the same line speeds and oven zone temperatures as in Example 1.

10          Next, the acrylic-based pressure-sensitive adhesive was prepared, cast, dried and laminated to the PVC color coat as described in Example 1. The same adhesive was also laminated to the construction that did not have the tie coat and PVC color coat.

15          Both constructions were tested for room temperature elongation. The average elongation value for the construction with no PVC color coat was 16%. The average elongation value for the construction with PVC color coat was 70%. These measurements showed that the addition of the PVC color coat enhanced elongation of the finished paint coated, adhesive-backed laminate.

20          The PVDF-acrylic color coat 50 contains a uniformly dispersed pigment which acts as a UV absorber and thereby reduces UV degradation of the underlying PVC-containing color coat 16. The pigments in the color coat 50 enhance opacity of the finished laminate, as well as the pigments in the color coat 16. UV stabilizers contained in the PVC color coat also provide an added level of UV protection for the PVC color coat. The PVC color coat contains a plasticizer for enhanced elongation. The pigment loading in the PVC color coat retains the plasticizer, inhibits its migration, and prevents intercoat adhesion failure.

25          As a result of this experiment, it was concluded that a PVC color coat was necessary for the paint coat construction, in order to provide adequate elongation values, along with the good exterior automotive properties of high gloss and DOI and weatherability provided by the composite PVDF-acrylic clear coat and the PVC-based color coat.

30

35

1     **WHAT IS CLAIMED IS:**

1.     A composite flexible decorative sheet for applying an exterior automotive paint finish to a substrate panel, comprising:

          a first flexible, heat-resistant carrier sheet;

5           a first coat comprising a smooth weatherable thin film formed on the first carrier sheet and comprising a blend of a fluoropolymer resin and an acrylic resin having durable exterior automotive property;

          a tie coat formed as a thin film on a side of the first coat opposite from the first carrier sheet;

10          an elongation-enhancing second coat formed as a thin film on a side of the tie coat opposite from the first coat, the second coat comprising a chlorinated polymer, the tie coat providing a means for bonding the first coat and the second color coat;

          a second flexible, heat-resistant carrier sheet;

15          a pigment dispersed in the second coat or in a separate color coat layer on a side of the second coat opposite from the first coat; thereby forming a composite paint coat in combination with the first and second coats;

          a layer of a pressure sensitive adhesive formed on the second carrier sheet and bonded to a side of the second coat opposite from the first coat, the adhesive layer being applied so that the smoothness of the first coat is not significantly reduced by the bonded adhesive layer,

20          the first and second carrier sheets forming removable protective outer sheets for composite paint coat,

          the first carrier sheet being removable from the first coat to expose the weatherable first coat,

25          the second carrier sheet being removable from the pressure sensitive adhesive for use in bonding the composite paint coat to a substrate panel,

          the second coat having sufficient elongation to enhance the elongation of the first coat so the composite paint coat has a level of elongation sufficient to conform to a three-dimensionally contoured shape of the substrate panel to which the adhesive layer is adhered for bonding the paint coat to the substrate as a smooth, durable, weatherable exterior automotive paint finish.

30           2.     The decorative sheet according to claim 1 in which the second coat includes a dispersed pigment and the first coat comprises an optically clear exterior layer through which the pigmented second coat is visible.

35           3.     The decorative sheet according to claim 1 in which the first coat contains a dispersed pigment; and in which the second coat contains a dispersed pigment, the pigment

1 contained in the first coat providing a level of UV absorption to protect the second coat from UV degradation.

4. The decorative sheet according to claim 3 in which the second coat contains a UV absorber and a heat stabilizer.

5 5. The decorative sheet according to claim 1 in which the tie coat comprises an acrylic-based resin.

6. The decorative sheet according to claim 1 in which the second coat is cast in liquid form on the tie coat and dried.

7. The decorative sheet according to claim 1 in which the clear coat has a thickness greater than about 0.8 mil to 1.4 mils.

8. The decorative sheet according to claim 1 in which the second coat includes a dispersed pigment, a heat stabilizer and a UV absorber.

9. The decorative sheet according to claim 1 in which the elongation of the composite paint coat is at least 50% and up to about 150% of the original size of the composite paint coat without said elongation significantly reducing the exterior automotive properties of the paint layer.

10. The decorative sheet according to claim 2 in which the composite paint coat has a distinctness-of-image greater than 60.

11. A method of forming a flexible decorative sheet for use in applying an exterior automotive clear coat/color coat paint finish to a substrate panel, comprising the steps of:

20 casting a clear coat comprising an optically clear, smooth, weatherable thin film on a first flexible, heat-resistant carrier sheet, the clear coat comprising a blend of a fluoropolymer resin and an acrylic resin, the clear coat film being dried on the first carrier sheet;

25 applying a tie coat as a thin film on a side of the clear coat opposite from the carrier sheet and drying the tie coat;

casting a color coat as a thin film on the tie coat opposite from the clear coat, the color coat comprising a chlorinated polymer containing a dispersed pigment, the tie coat bonding the color coat to the clear coat;

30 separately forming a layer of a pressure sensitive adhesive on a second flexible, heat-resistant carrier sheet, followed by laminating the pressure sensitive adhesive to a side of the color coat opposite from the clear coat, and leaving the first and second carrier sheets adhered to the clear coat and pressure sensitive adhesive layer, respectively, to provide removable protective outer sheets for a flexible, self-supporting composite paint coat comprised of the clear coat, the tie coat and the color coat;

35 removing the second carrier sheet from the adhesive layer and adhering the pressure sensitive adhesive side of the color coat to a substrate panel; and

1 removing the first carrier sheet from the clear coat to expose the clear coat as  
a glossy automotive quality paint coat with the color coat visible through the clear coat;

the color coat having sufficient elongation to enhance the elongation of the clear  
coat so that the composite paint coat has a level of elongation sufficient to conform to a three-  
5 dimensionally contoured shape of the substrate panel to which the adhesive layer of the paint  
coat is bonded for forming a defect-free, smooth, glossy, weatherable exterior automotive  
paint finish on the substrate.

12. The method according to claim 11 in which the composite paint coat has a DOI  
greater than 60.

10 13. The method according to claim 12 in which the DOI is greater than 90.

14. The method according to claim 11 in which the composite paint coat includes  
a first color coat comprising a blend of a fluoropolymer resin and an acrylic resin containing  
a dispersed pigment, the first color coat being bonded between the clear coat and the tie coat;  
and in which the thermoplastic color coat comprises a second color coat, the pigment  
15 contained in the first color coat providing a level of UV absorption to protect the second color  
coat from UV degradation, the tie coat bonding to the second color coat.

15. The method according to claim 14 in which the second color coat contains a  
UV absorber and a heat stabilizer.

16. The method according to claim 11 in which the carrier sheets comprise a  
20 polyester film.

17. The method according to claim 11 in which the adhesive layer is cast on the  
second carrier sheet and dried, and in which the second carrier sheet is a polyester film.

18. The method according to claim 11 in which the color coat contains a plasticizer  
and a pigment such that Volatile Haze of the decorative sheet is sufficiently reduced that post-  
25 process heat treatment is omitted.

19. The method according to claim 11 in which the color coat includes a UV  
absorber and a heat stabilizer.

20. The method according to claim 11 in which the color coat includes a plasticizer  
having a molecular weight greater than about 7,000.

21. The method according to claim 20, in which the plasticizer comprises a  
30 polyester azelate.

22. The method according to claim 11 in which 20 degree gloss retention was  
within 20% of its initial gloss measurement for a decorative sheet subjected to Volatile Haze  
testing.

## INTERNATIONAL SEARCH REPORT

International application No.

PCT/US93/10628

## A. CLASSIFICATION OF SUBJECT MATTER

IPC(5) : B32B 7/12, 15/04; B65D 65/28

US CL : 428/40, 343, 346, 352, 353, 354, 355

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 428/40, 343, 346, 352, 353, 354, 355

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	WO, A, WO 88/07416 (AVERY INTERNATIONAL CORPORATION) 06 OCTOBER 1988. See entire document.	1-22
Y	US, A, 4,931,324 (ELLISON ET AL) 05 JUNE 1990. See entire document.	1-22

Further documents are listed in the continuation of Box C.

See patent family annex.

*A*	document defining the general state of the art which is not considered to be part of particular relevance	*T*	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
*E*	earlier document published on or after the international filing date	*X*	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
*L*	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*Y*	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
*O*	document referring to an oral disclosure, use, exhibition or other means	*Z*	document member of the same patent family
*P*	document published prior to the international filing date but later than the priority date claimed		

Date of the actual completion of the international search

21 JANUARY 1994

Date of mailing of the international search report

24 FEB 1994

Name and mailing address of the ISA/US  
Commissioner of Patents and Trademarks
